APS106

UNIVERSITY OF TORONTO

Lists: indexing and slicing.

Week 7 | Lecture 1 (7.1)

While waiting, open the Jupyter Notebook for today's lecture

Upcoming.
- Lab 5 Released Thursday 6:00 pm.
- Reflection 7 Released Friday 6:00 pm.
- Tutorial (in-person AND online) running all week.
- Practical sessions (in-person AND online) running ONLY Friday this week.

if nothing else, write #cleancode

This Week's Content

- **Lecture 7.1**
  - **Lists: indexing and slicing**

- **Lecture 7.2**
  - Lists: nested lists and looping

- **Lecture 7.3**
  - Design Problem! Connect 4

Online Tutorial

- These times worked best for you!
  - TIP FOR SUCCESS: Put these in your calendar! Labs are due Friday night!
- Schedule and Zoom Links are on Quercus
  - "Tutorial Homepage"

	Time
Tutorial	Wednesday 7 – 8 PM

Commuting

Online Tutorials

Coffee Break with a TA!

- Extra help hours!
  - TIP FOR SUCCESS: Put in calendar, treat as a scheduled class
- Schedule and Zoom Links are on Quercus
  - "Coffee Break (Office Hours)"

Teaching Team	Time	Mode
Ben & Seb	Fridays 2 - 3 PM	MY765
Michael Tisi	Fridays 10 - 11 AM	Online
Thomas Pruyn	Mondays 3-4 PM	WB255 and Online
Mo Saneii	Tuesdays 3 - 4 PM	Online
Rachel Leung	Wednesdays 2-3PM	GB144 and Online
Hosein Seyed Ghafouri	Mondays 5 - 6 PM	Online

Office Hours

Coffee Break

Next Midterm: March 18

TLDL: Be like Gandalf, not Austin Powers

Motivation

We want to keep track of characters in a complex show/book

✓Name

✓Actor

✓Personality

✓Age

✓Title/Powers

- We could store values in a string?
- We could have unique variable names for each person?

```
gandalf_age = 24000
frodo = "Frodo-Elijah Wood-brave, observant, and unfailingly polite-51-Ring bearer"
```

We need an efficient way to do this.

Motivation

- We could store values in a string or other individual variables?

```
gandalf_name = "Gandalf the Grey"
gandalf_age = 24000
#all other values for Gandalf in separate variables
```

- We could have unique variable names for each person, including name, actor, personality, age and power?

```
frodo = "Frodo-Elijah Wood-brave, observant, and unfailingly polite-51-Ring bearer"

#we could use frodo.split('-') or frodo.find('-') to split at or find the dashes
```

- We need a more efficient way to do this

One way: Tables or Lists!

| Name	Actor	Personality	Age	Powers
Sam				
Frodo				
Gandalf				
Galadriel				
Pippin				
Aragorn				
Legolas				
Eowyn				
Gollum				
Arwen				
Merry				

Need to:
- ✓ Create rows of data
- ✓ Create columns of data
- ✓ Be able to access a specific cell/index

Data Structures!

Data structures are "containers" that organize and group data

- Lists
- Sets
- Tuples
- Dictionaries
- Custom classes/objects
- Linked lists
- Binary trees
- Stacks
- Queues
- Arrays
- Heaps
Type: List

- Can store an **ordered** collection of data using Python's type list
- The general form of a list is:

```
[val1, val2, val3, …, valN]
```

- Values are enclosed in ([ ]) and separated by commas (,)
- Can assign lists to a variable name:

```
my_list = [val1, val2, val3, …, valN]
```

List Elements

- list elements can be of any type:

```
subjects = ['bio', 'programming', 'math', 'history']

grades = [75, 98, 82, 62]
```

- A list can contain elements of more than one type:

```
street_address = [10, 'Main Street']

light = ['status', True, 'intensity', 3.1]
```

List Operations (Indexing and Slicing)

- A list can be indexed just like a string:

```
>>> grades = [80, 90, 70, 45, 98, 57]
>>> grades[1]
90
>>> grades[-3]
45
```
- A list can be sliced just like a string:

```
>>> grades[0:2]                      >>> grades[::-2]
[80, 90]                             [57, 45, 90]
```

Nested Lists

- Lists can contain any type, including other lists!
    - Called "nested lists"

```
[list1, list2, …, listN]
```

```
[val1, val2, …, valN]
```

- To access a nested item, first select the sublist, then treat as a regular list

```
>>> list_of_lists[0]
[val1, val2, …, valN]
>>> list_of_lists[0][1]
val2
```

YO DAWG, I HEARD YOU LIKE LISTS

SO I PUT A LIST IN YOUR LIST
SO YOU CAN STORE DATA IN YOUR DATA

Nested Lists Example

- Let's provide some information in our list of grades:

```
>>> aps106_grades = [['Midterm 1', 60],['Midterm 2', 90],['Exam', 100]]

>>> aps106_grades = [['Midterm 1', 60],
                     ['Midterm 2', 90],
                     ['Exam', 100]]
```

BOTH OF THESE ARE THE SAME THING!

- Now we can access different parts depending on what we want:

```
>>> aps106_grades[0]
['Midterm 1', 60]

>>> aps106_grades[2][1]
100
```

Let's Code!

- Let's take a look at how this works in Python!
  - Creating lists
  - List indexing and slicing
  - List operations
  - Nested lists!

Open your notebook

Click Link:
1. The 'list' Type

List Mutability

- Lists are mutable!
  - This means they can be mutated (modified)

- All the other types we've learned so far (string, int, float, and bool) are immutable (i.e. they can NOT be modified)

List Mutability Example

strings are
immutable

```
>>> s = "I love cats"
s[0] = "U"
Traceback (most recent call last):
builtins.TypeError: 'str' object does not
support item assignment
```

lists are
mutable

```
>>> grades = [80, 90, 70, 45, 98, 57]
>>> grades[3] = 100
>>> grades[-1] = 100
>>> grades[2] = 'Perfect'
>>> grades
[80, 90, 'Perfect', 100, 98, 100]
```
Aliasing

- When two variable names refer to the same object, they are aliases.
- When we modify one variable, we are modifying the object it refers to, hence also modifying the second variable.

- This is common source of error when working with list objects.

Aliasing Example (with Visualizer)

Permalink:

https://tinyurl.com/aps106alias

Avoiding Aliasing

```
>>> lst1 =   [11, 12, 13, 14, 15, 16, 27]
>>> lst2 = lst1
>>> lst1[-1] = 17
>>> lst2
[11, 12, 13, 14, 15, 16, 17]

>>> id(lst1)
49012568
>>> id(lst2)
49012568
```
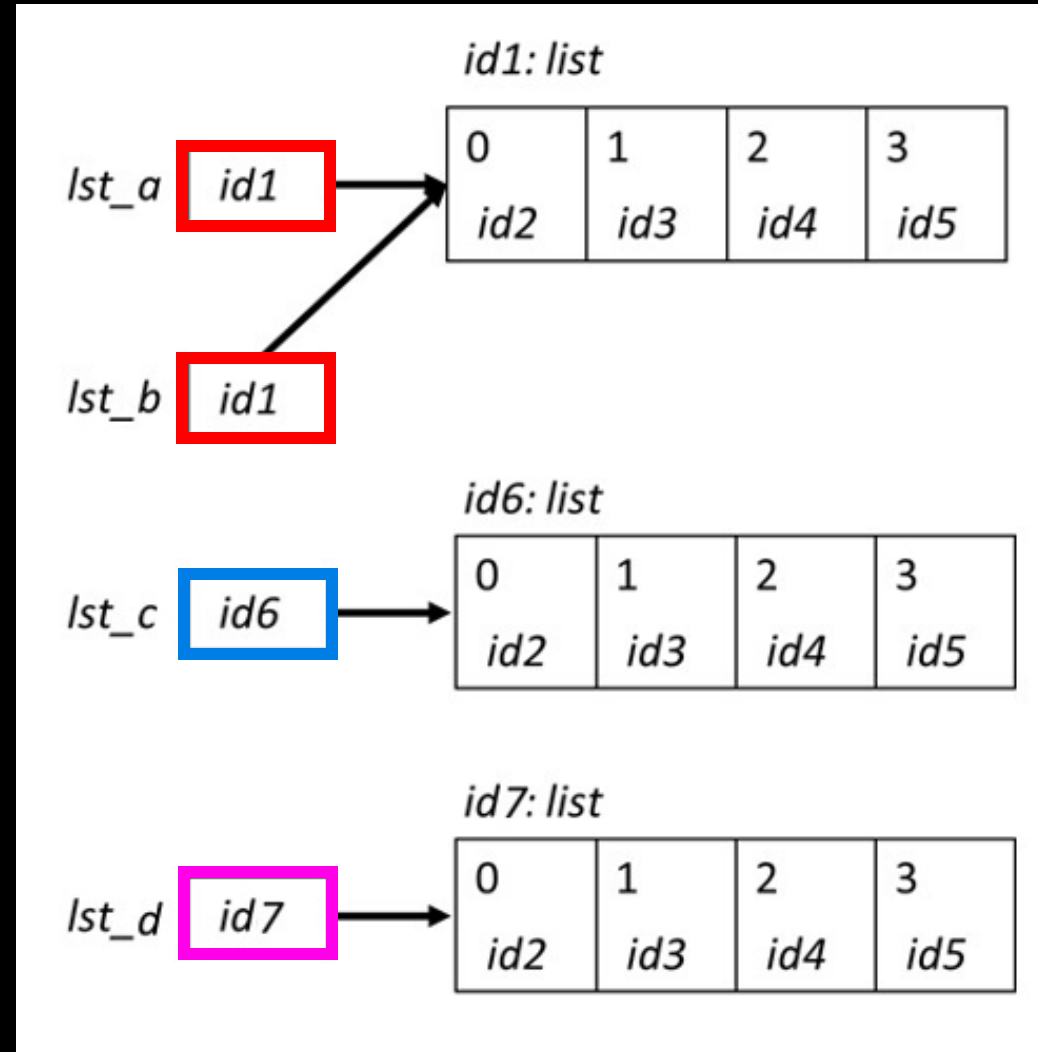

▪ How can we copy lst1 into another list without aliasing?

Copying Lists and Avoiding Aliasing

- There are two simple ways to copy lists:
  - Using the `list( )` function
  - Completely slice the list `[:]`

```
>>> lst_a =  [0, 1, 2, 3]
>>> lst_b = lst_a
>>> lst_c = list(lst_a)
>>> lst_d = lst_a[:]

>>> id(lst_a)
39012510
>>> id(lst_b)
39012510
>>> id(lst_c)
54514112
>>> id(lst_d)
24514139
```

2. Mutability and Aliasing

Built-in Functions

- Several of Python's built-in functions can be applied to lists, including:

  - `len(list)` : return the number of elements in list (i.e. the length)
  - `min(list)` : return the value of the smallest element in list.
  - `max(list)` : return the value of the largest element in list.
  - `sum(list)` : return the sum of elements of list (list items must be numeric).

List Methods

- Lists are objects and just like other objects, the list type has associated methods that are only valid for lists

- Recall you can find out which methods are associated with objects using the built-in function dir

```
>>> dir(list)

['__add__', '__class__', '__class_getitem__', '__contains__',
'__delattr__', '__delitem__', '__dir__', '__doc__', '__eq__',
'__format__', '__ge__', '__getattribute__', '__getitem__', '__gt__',
'__hash__', '__iadd__', '__imul__', '__init__', '__init_subclass__',
'__iter__', '__le__', '__len__', '__lt__', '__mul__', '__ne__',
'__new__', '__reduce__', '__reduce_ex__', '__repr__', '__reversed__',
'__rmul__', '__setattr__', '__setitem__', '__sizeof__', '__str__',
'__subclasshook__', 'append', 'clear', 'copy', 'count', 'extend',
'index', 'insert', 'pop', 'remove', 'reverse', 'sort']
```

Adding Items to a List

- To add an object to the end of a list, use the list method append:

```
>>> colours = ['blue', 'yellow']
>>> colours.append('brown')
>>> colours
['blue', 'yellow', 'brown']
```

- To add a list to the end of a list, use the list method extend:

```
>>> colours = ['blue', 'yellow']
>>> colours.extend(['pink','green'])
>>> colours
['blue', 'yellow', 'pink', 'green']
```

Removing Items from a List

- To remove an object from a list, use the list method remove:

```
>>> colours = ['blue', 'yellow', 'pink']
>>> colours.remove('yellow')
>>> colours
['blue', 'pink']

>>> colours.remove('red')

Traceback (most recent call last):

builtins.ValueError: list.remove(x): x not in list
```

How can we write it so there's no error?

Is something in my list?

- The in operator can be used on lists too!

```
colours = ['blue', 'yellow', 'pink']

if 'red' in colours:

    colours.remove('red')
```

Let's Code!

- Let's take a look at how this works in Python!
